

General aim: Anticipate the geomorphic response of steep alpine rock walls following glacier retreat

<p>Background</p>	<p>The focus of the proposed research is on recently deglaciating and rapidly reacting, unstable rock slope systems that may endanger people and infrastructure in the near future. These rock slope systems share a distinct topography but differ in material properties, experience fundamental cryospheric change and thus destabilise by a multitude of processes, ultimately leading to failure. Following a multi scale approach, each of these different aspects of rock slope instability is addressed by a specified work package presented below.</p>																																											
<p>Work Packages</p>	<p>(i) Preconditioning</p>	<p>(ii) Destabilising Processes</p>	<p>(iii) Rock Slope Failure</p>																																									
<p>Specific Aims</p>	<p>Where rock slopes respond rapidly to glacier retreat may depend largely on their inherent conditions such as topography, rock structure and lithology. The aim is to identify and characterise cirque glacier headwalls on a broad spatial scale by their topography, geology, permafrost occurrence and glacial occupation.</p>	<p>As soon as formerly glaciated rock slopes are exposed, destabilising processes such as frost cracking and thermomechanical deformation initiate or intensify. A novel monitoring setup enables to decipher and quantify destabilising processes in a recently deglaciating and highly unstable headwall section at the Open Air Lab Kitzsteinhorn.</p>	<p>To date, datasets of rockfall from recently deglaciating headwalls barely exist, but pioneering studies point towards an immediate response of freshly exposed rock surfaces. Extensive laserscanning campaigns at four different cirque settings aim to detect and quantify rockfall and reveal which headwall characteristics most significantly affect instability.</p>																																									
<p>Methods</p>	<p>Object-based image analysis (OBIA) for headwall detection and GIS-based approach for further headwall characterisation</p> <table border="1" data-bbox="519 1249 1098 1543"> <thead> <tr> <th rowspan="2">Data input</th> <th colspan="2">Topography</th> <th colspan="2">Geology</th> <th colspan="2">Cryospheric conditions</th> </tr> <tr> <th>Slope</th> <th>Aspect</th> <th>Dip</th> <th>Direction</th> <th>Glaciers</th> <th>Permafrost</th> </tr> </thead> <tbody> <tr> <td>Merge</td> <td>→</td> <td>→</td> <td>→</td> <td>→</td> <td>Distance to Glacier/ Time since Deglaciation</td> <td>High probability Low probability No permafrost</td> </tr> <tr> <td>Classify</td> <td>→</td> <td>→</td> <td>→</td> <td>→</td> <td>→</td> <td>→</td> </tr> <tr> <td>Data output</td> <td>→</td> <td>→</td> <td>→</td> <td>→</td> <td>→</td> <td>→</td> </tr> <tr> <td>Sensitivity</td> <td>very high</td> <td>high</td> <td>medium</td> <td>low</td> <td>very low</td> <td>Stability increase/ decrease</td> </tr> </tbody> </table> <div data-bbox="1270 1207 1982 1543"> <p>Monitoring of fracture kinematics with high-resolution crackmeter devices at the north face of the Kitzsteinhorn</p> </div> <div data-bbox="2062 1291 2843 1543"> <p>Ödenwinkelkees</p> </div>			Data input	Topography		Geology		Cryospheric conditions		Slope	Aspect	Dip	Direction	Glaciers	Permafrost	Merge	→	→	→	→	Distance to Glacier/ Time since Deglaciation	High probability Low probability No permafrost	Classify	→	→	→	→	→	→	Data output	→	→	→	→	→	→	Sensitivity	very high	high	medium	low	very low	Stability increase/ decrease
